10716. Proposed by Michael L. Catalano-Johnson and Daniel Loeb, Daniel Wagner Associates, Malvern, PA. What is the largest cubical present that can be completely wrapped (without cutting) by a unit square of wrapping paper?

10717. Proposed by Marcin Mazur, University of Chicago, Chicago, IL. We say that a tetrahedron is rigid if it is determined by its volume, the areas of its faces, and the radius of its circumscribed sphere. We say that a tetrahedron is very rigid if it is determined just by the areas of its faces and the radius of its circumscribed sphere.

- (a) Prove that every tetrahedron with faces of equal area is rigid.
- (b) Prove that a very rigid tetrahedron with faces of equal area is regular.
- (c)* Is every tetrahedron rigid?
- (d)* Is every very rigid tetrahedron regular?

SOLUTIONS

Subtracting Square Roots Repeatedly

10568 [1997, 68]. Proposed by Donald E. Knuth, Stanford University, Stanford, CA. Let n be a nonnegative integer. The sequence defined by $x_0 = n$ and $x_{k+1} = x_k - \lceil \sqrt{x_k} \rceil$ for $k \ge 0$ converges to 0. Let f(n) be the number of steps required; i.e., $x_{f(n)} = 0$ but $x_{f(n)-1} > 0$. Find a closed form for f(n).

Solution by Denis Constales, University of Gent, Gent, Belgium. Every positive integer n can be written uniquely in the form p^2-q , where p and q are integers satisfying $p \ge 1$ and $0 \le q \le 2p-2$ (take $p = \lceil \sqrt{n} \rceil$ and $q = p^2-n$). We call this standard form for n. We obtain the desired formula in terms of these parameters p and q.

Using standard form, let $n' = n - \lceil \sqrt{n} \rceil = p^2 - (q+p)$. We distinguish two cases. **Case 1:** $p-1 \le q \le 2p-2$. We rewrite n' as $(p-1)^2 - (q-(p-1))$. Since $q \ge p-1$, this expresses n' in standard form with p' = p-1 and q' = q - (p-1) (when p > 2). **Case 2:** $0 \le q \le p-1$. Now $n' = p^2 - (q+p)$ is standard form for n' with p' = p and q' = q + p. The next value $n'' = n' - \lceil \sqrt{n'} \rceil = p^2 - (q+2p)$. Expressed in standard form, this is $n'' = (p-1)^2 - (q+1)$ (when p > 2).

We have applied the transformation once in Case 1 and twice in Case 2. Thus

$$f(p^2 - q) = \begin{cases} 2 + f((p-1)^2 - (q+1)) & \text{if } 0 \le q \le p-2\\ 1 + f((p-1)^2 - (q-p+1)) & \text{if } p-1 \le q \le 2p-2 \end{cases}$$

whenever p > 2 and $0 \le q \le 2p - 2$. The cases $p \le 2$ occur for $n \in \{1, 2, 3, 4\}$, where f(n) = 1, 1, 2, 2, respectively. With the recurrence, these initial conditions define f. Our closed form is

$$f(p^2-q) = \begin{cases} 2p - \lfloor \log_2(p+q) \rfloor - 1 & \text{if } 0 \le q \le p-1 \\ 2p - \lfloor \log_2 q \rfloor - 2 & \text{if } p \le q \le 2p-2 \end{cases}$$

for integers p, q such that $1 \le p$ and $0 \le q \le 2p - 2$. Also, we set f(0) = 0.

The proof of the formula is immediate by induction, using the recurrence in the three cases $0 \le q \le p-2$, q=p-1, and $p \le q \le 2p-2$. The only simplification needed occurs in the second case, where $\lceil \log_2(2p-1) \rceil = 1 + \lceil \log_2(p-1) \rceil$, which follows immediately when p > 1.

Editorial comment. Robin J. Chapman and the GCHQ Problems Group expressed f(n) using the single formula $f(n) = \lfloor 4n + 2^{m+3} - 3 \rfloor - (m+2)$, where $m = \lfloor \log_2(\sqrt{n} + 1) \rfloor$.
